

Chlorophanes, I.

(1)

November 30, 1957,
Barro Colorado

This species may not be uncommon around the clearing on the island, but it is certainly not conspicuous. I have seen a number of ♂'s (all adult in complete plumage, except one bird, presumably immature, in which the bluish of the head was very "spotty") in both moderately low-vegetation and the tree-tops. Always solitary. One came to "visit" the captive birds very briefly once, without doing anything of interest, but otherwise they have been very aloof.

Chlorophanes, I.

December 1, 1957
Barro Colorado

A ♀ just showed up to "visit" Guffy. Gave a "test" on as it flew away. Otherwise no display of any kind.

Chlorophanes, I.

December 21, 1957
Barro Colorado

Trapped one ♀ today (Banded red right), and released her this evening.

She was, and still is, quite nervous. Flying about quite a lot. Surprisingly enough, she is quite silent during this flying about. Even after being in the cage 4 or 5 hours. Blue Honeycreepers of both sexes would cut in, utter lots of

Chlorophanes, Dec. 21, 1957, II.

||| CN's and/or HCN's in similar circumstances.

Once, soon after being let loose, she paused, set for a few minutes, and uttered a lot of single, rather loud "Tut" notes, (bill opening & closing with each note) from a perfectly untroubled sitting posture.

I have heard wild birds utter similar "Tut's", when sitting, and (I think) when flying by me.

The fact that the captive ♀ did not utter "Tut's" when flying around would suggest that they are ALCN's and not ordinary CN's.

||| I have seen no trace of a distinct CR pattern like that of the Blue Honeyeepers.

The captive ♀ has the usual tanager WF's and TF's. When she was flying about at her nest visited, she gave several distinct G's (revealing yellow inside mouth) when she landed, mounting, & particularly when

Chlorophanes, II

December 23, 1957,
Barro Colorado

The captive ♀ is not very active; much less so than the Blue Honeyeepers or the Tropicbirds (at least in the morning).

Tends to sit a lot, all fluffed out, looking very large headed.

and relatively small-headed

When she does have periods of flying about, she often assumes the posture drawn above before flying up. This may help

Chlorophanes, Dec. 23, 1957, II

(3)

to explain the evolution of the st. of the Blue Honeycreepers — although they don't assume this posture as a pre-flight pattern nearly as often as Chlorophanes.) In the case of this ♀ Green Honeycreeper, at least, this pre-flight "bill-up" posture does not appear to be ritualized in physical form.

This ♀ is still largely silent when she flies about, although she does give single "Trit's" from time to time. Most of her "Trit's" are given while she is sitting still. This afternoon, I couldn't detect much hostility while she was "Trit"-ing. The notes looked very much like the results of frustrated gregariousness or sexuality.

The ♀ often does OCB (slower than that of gulls), and rapidly extends & withdraws the tongue repeatedly, in circumstances of "stress". This may be more than coincidence.

Chlorophanes, I

December 28, 1957
Barro Colorado

I swear that the captive ♀ just opened its bill wide and uttered an absolutely mechanical sounding rattle, when another bird came too close. No ritualized postures, or movements.

An adult ♂ in perfect plumage came to visit the captive ♀ this afternoon. I tried again & again to get into the aviary. Almost completely silent, just a few "Trit's" from time to time, and I couldn't be sure what stimulus provoked them.

Chlorophanes, I

December 30, 1957
Barro Colorado

Chlorophanes, Dec 30, 1957, I

(4)

Caught a new ♀ Green Honeycreeper today. Banded white
ring. Put in aviary.

When I was taking it out of the net, it uttered a lot of hoarse
harsh notes possibly HAC, but rather loud sometimes single,
sometimes in series of up to 5 or 6, but the series were never organized
into distinct units.

When I put it into the aviary, both it and the earlier ♀ were
rather excited, flying about. Both of them uttered some "Tuts", but
were comparatively silent on the whole. Both of them also did a lot
of G-wug; but it was difficult (as usual) to determine if this was
really a ritualized signal. They simply have been a reaction to the
elevation of flying about — but, if so, this species "parts" much
more easily than any of the others I am studying.

I did notice that when another Green Honeycreeper came to
"visit" both the captive birds started to fly about and give
"Tut"s at moderately frequent intervals. The captive birds and
the wild bird seemed to be responding to one another, calling
back & forth.

The 2 captive ♀'s are really having nothing to do with
one another.

Chlorophanes, I

December 31, 1957,
Barro Colorado

A wild ♂ and several ♀'s have come to visit the
captive ♀'s this morning. Most of the visitors have not done
much, just "Tut" Notes & Hells. One of the visiting ♀'s,

Chlorophanes, Dec 31, 1957, II.

(5)

Became very excited, flew back & forth, uttered a lot of Trits and did a lot of Flushing. Twice again she also uttered a very loud mechanical sounding Rattle (much louder than the one I heard the captive ♀ give a few days ago). Like a lot of Trits run together. The bill vibrated or opened & closed very rapidly in unison with the Rattle Notes. I think that the lower mandible vibrated more than the upper. In any case, the yellow on the lower mandible and inside the mouth flashed conspicuously during the Rattle. It was not, however, accompanied by any other particular or peculiar ritualized posture or movement (except for Flushing, of course) I think that the Rattle must be a hostile pattern, probably threat.

There were a few calls which seemed to be nicely intermediate between the Rattle and the ordinary Trit. A single Trit note, followed immediately (like an echo) by 3 or 5 Rattle Notes.

The full Rattle must include at least 10 or 15 notes. The whole Trit - Rattle complex is rather reminiscent of the trillers of the genera Tangara.

I have now seen a visiting ♂ give a full Rattle just like that of the visiting ♀ earlier. Again without ritualized postures or movements.

Chlorophanes, I.

January 2, 1958,
Barro Colorado

Let us call Rattle R.

Chlorophanes, Jan. 2, 1958, I.

(6)

I have heard lots of R's given by the 2 captive ♀'s this morning when there were no wild birds around. Probably some of them provoked by other species in the aviary. Another indication that it may be a purely territorial pattern.

A wild ♂ came & R'd at the captive birds very briefly this morning. Much as before. I did notice, however, that his tail vibrated in rhythm with the call, and that his head feathers, although not ruffled at all, were perhaps slightly fluffed. Anyhow, from the front, the whole head (except bill, of course) looked completely black, comme ça:

Yes! I have just seen one of the captive ♀'s give an R while attacking a Euphonia over food.

So far this species seems to be unusually unlike the Blue Honeycreepers.

The R can certainly be given in flight.

Several more cases of captive ♀'s using R when attacking other birds over food. Must certainly be relatively very aggressive.

This afternoon I caught an adult ♂, banded light blue right. Perfect plumage.

When I put him in the aviary, he didn't do much except fly about excitedly, very scared. Settled down quite quickly, but relaxed at the same time. Not interesting.

The 2 captive ♀'s also flew about excitedly when he was put in. Both did a little R, but the white right ♀

Chlorophanes, Jan. 2, 1957, II

7

did much more than the other ♀. Some of her R's were directed toward the new ♂, but most of them were directed toward birds of other species. As she did much more R at this time than the other otter captive ♀ has ever done before, I presume that a lot of her R was reduction.

Later on a wild ♂ came to visit the captive birds
and behaved in a way I have never seen before. Quite
neut Most of the time spent with the back and breast
and belly feathers very fluffed, really ruffled. Part of the
time this "Gfluff" was combined with a very white-
alized flight sit-mos. Part of the time it was combined
with a sort of "upright alert" posture. The latter combina-
tion I shall call the Vgfluff. You sitting, coming

You lead high

Head & neck sometimes included
for anal also

All the fluff (both with and without) was combed with very frequent and extreme flicking of the usual type and all sorts of comfort movements: i.e. preening (back & over shoulders), scratching (side of head), wing shaking or vibratting (rare), bill-wiping (common), and rubbing the side of the head against a twig. Also CCB, and a sort of lateral flicking in and out of the tongue.

The outside the edge colored with yellow wash

Allophorus, Jan 2, 1958, II.

(8)

with lots of flicking and comfort movements, but without any signs of the Gfluff (perhaps a slight trace of V or alert posture, but not much).

I presume that this whole complex of patterns, or at least much of it, was less aggressive than the previous hostile encounters I have seen. No R. Presumably the ♂'s were somewhat frightened of one another. (This is the first hostile encounter I have seen, in which ♂'s were involved.)

Another visiting ♂ just showed up, and again displayed toward the captive ♂ with Vgfluff and associated patterns. Just as before. (But I think that the bill is usually, perhaps inclined slightly upward during the extreme Vgfluff - although this varies greatly, according to the position of the opponent, and the strength & frequency of the accompanying comfort movements. A ♂ in Vgfluff will often look down, like the "Bill-down" of Larks, in what is apparently an int. mov. of Bill-upping, or preening or something). Then a second visiting ♂ showed up while the first was still present! The 2 visiting ♂'s then went flitting off into the trees, hopping excitedly from twig to twig, and flung each other in Vgfluff every time they landed!

The captive ♂ responded to the visitors as before, except that this time he once went into a Vgfluff in return, and, later on, gave an R (with perhaps a slight trace of Gfluff - but nothing more).

After the 2 visiting ♂'s had gone, another ♀ came to visit. She just did R without any actualized postures or movements except flicking.

Chlorophanes, Jan. 2, 1958, IV.

⑦

Getting the birds in the aviary has been a revelation in one sense. They do not seem to be gregarious in the wild. (I have never seen more than 3 wild birds moderately close together in the wild, and that may only very rarely). But the captive birds certainly do seem to have the power of "attraction", pulling in lots & lots of visitors, some of them probably repeatedly (I might add that I have also caught another visitor ♀ today, which I shall let go later on.)

Before I forget completely, I should add that the "obvious territorial flight int. notes." with which the visitors ♂'s have combined the Vgfluff are nothing more than a flexing of the legs and a stretching forward (and sometimes downward) of the head & neck.

Another visitor ♀ has just appeared, and has sat for some minutes now on a branch just above the aviary. In perfectly relaxed, rather hunched, sitting posture, uttering "Tut" Notes at not too infrequent intervals. So these "Tut" Notes can't be a sign of great alarm.

Another ♂ coming to visit!! Behaving just as before. The captive ♀'s are certainly dominant over the captive ♂ at present. They can always force him to retreat, by a simple supplanting attack or a supplanting attack + R.

The captive ♂ has behaved like the ♀'s so far as he has given few or no "Tut" Notes.

Another visit by a ♂!! Behaving more or less as before I notice that OCB and "tongue pumping" are almost constant during the Vgfluff by the visitor this time.

Another visit by a ♀, who does nothing at all.

Chlorosp. hawaii, II.

(10)

January 3, 1957,
Barro Colorado

I have caught 2 more adult ♂'s this afternoon, and put them in the aviary. Banded yellow right, red black left.

When I put them in the aviary, they did nothing but fly about in the usual escape reactions. No sign of R or Gfluff. Possibly no "Ints" — certainly very few. Would seem to indicate that all these reactions need some appreciable attack drive in order to be produced.

In general, all the captive Green Honeycreepers, ♀'s as well as ♂'s, seem to try to stay as far away from one another.

I have seen more cases of ♀'s attacking other birds with soft brief R's. And one case of a ♂ trapping with a similar R!

I think there is a morphological distinction between low-intensity and high-intensity R patterns. The shortest R's are softer, lower-pitched (?), with less visible vibration of mandibles — I think — than the longer R's. I have also heard some long R's which began in an apparently "low intensity" way, and then developed into the apparently "high intensity" type — so it is possible that the differences between the 2 types are the result of differences in relative aggression.

I am almost sure, now, that the so-called "Gaping" of this species is not a ritualized display.

The posture of a perfectly relaxed bird, half asleep, is very fluffed; but it differs from the Gfluff in that the lower back and rump feathers are perhaps the most fluffed of all.

Chlorophanes, I

(11)

January 4, 1958
Barro Colorado

My My! The red-right captive ♀ has become unbelievably aggressive this morning. Attacks every other honeycreeper and Euphonia who comes anywhere near the food dish sometimes chases them back & forth (particularly the ♂ Green Honeycreepers). Usually ignores the finches, even when they come very close to the fruit dish (more than close enough to provoke vigorous attack were they fruit-eaters).

All these attacks were eventually supplanting. Either silent or with brief "low intensity type" R (call this SR). In other words, the SR is not really a relatively low intensity patter, compared with the longer, louder R's (LR), but only a sign of relatively weak conflict — can occur when the attack drive is relatively very strong.

None of the other Green Honeycreepers has fought or displayed back at all.

My God! What a day! This fighting continued for a few minutes more, when I suddenly noticed that 2 ♂'s were on the floor of the aviary. Either exhausted, or injured, or suffering from stroke. The yellow-right & black-left ♂'s. I picked them up and tried to restore them, but they both died very soon! So I took the red-right ♀ out of the aviary, and put her in a separate cage — whereupon the white-right ♀ began to behave in just the same way! Chasing all the fruit-eaters on sight! So I took both the remaining Green Honeycreepers out

Chlorophanes, Jan 4, 1957, II

(17)

of the aviary and put them in the cage with the red-right ♀. Whereupon the red-right ♀ started to chase the white-right ♀ unmercifully (rather ignoring the remaining ♂, thank God!).

I heard one of the ♂'s give 2 hoarse, harsh notes, like the notes given by birds in the net when handled when escaping from one of the attacking ♀'s in the aviary! sounded just like the HAC of other species, but I shall call it HC. Similar notes were uttered when the red-right was chasing the white-right in the small cage. And there was a whole burst of such notes when the 2 ♀'s got involved in a real knock-down-and-drag-out fight. This pattern must be very high intensity! And probably contains a very strong escape component.

God alone knows what started this elimination bout this morning! It may be that the birds were merely getting used to the aviary. Or, perhaps more probably, it may have been a sudden up-surge of "reproductive" behavior. It was very cold & rainy all morning long — much more so than it has been for weeks (at least) — and the birds may have thought the rainy season was starting again or anew. (See also today's notes on Guanapes.)

No wonder these birds don't appear to be very gregarious when seen in the wild!

It might be noted that one or more of the surviving birds is now uttering a lot of "Frit" Notes in the new small cage.

It might also be noted that I saw very few, if any, "crest alarm" postures during all this brou-ha-ha. The frightened birds usually sat hunched, with head & bill pointing forward.

Chlorophanes, I

(13)

January 8, 1958
Barro Colorado

Everything seems to be moderately quiet in the small cage. The 2 ♀'s and the surviving ♂ (with injured wing) are getting along more or less all right, with lots of supplanting attacks, & few fights, quite a bit of R and Tait's ♀'s are still strongly dominant.

I have been watching Flicking in these birds too. Quite variable, as usual, but more or less like that of the Blue Honeycreepers. Lots of quite extreme WF. Very little TF, and that possibly unanalyzed. When it does occur, eventually or completely a direct lateral movement, usually a continuation of a head movement followed a slight vertical component, usually V-D, perhaps some times D-V.

Chlorophanes, I

January 15, 1958,
Barro Colorado

Today I watched a wild ♀ chase a wild ♂, when a whole flock of birds (of many species) was feeding in a Cecropia. She gave R as she attacked, and the ♂ fled immediately. This is one of the very few cases of overt aggression I have seen among the wild tanagers - so far.

Chlorophanes, I

January 23, 1958,
Barro Colorado

2

Nothing very new or spectacular recently.

Chlorophanes, Jan 23, 1958, I

(14)

Wild birds still come in to visit. No capture was from time to time. A ♀ came in this morning, and did the complete Vgfluff pattern just like the ♂'s described on Jan 2, & 7. With lots of WF, as apparently usual in this pattern. (But very little and very un-exaggerated TF - is this also usual? I think perhaps no.) Also with lots of BW and pecking-in-and-out of the tongue.

This is the first of the very numerous ♀ visitors I have seen do this. It is probably significant that she did this when I was not near the cage (I was watching from the top of the hill) - the only ♂'s I saw do this pattern also did it while I was away (in the house). This would certainly suggest that the pattern cannot occur when the escape drive is as strong as it always is when a human being is present.

Chlorophanes, I

February 1, 1958
Panama

Watching a whole swarm of honeycreepers, both green & blue (see today's notes on Cyanerpes), disputing in the Palma by Chapman House. At least 2 pairs of Greens, squabbling among themselves and also attacking all the Blues, chasing frantically round the tree. The whole dispute lasted about a half hour. The Green ♂'s did a little Vgfluff and a little R during both the inter- and intra-specific disputes, (the Vgfluff with lots of WF as usual), but ritualized patterns in general were rare as attacks or supplanting attacks were relatively seldom resorted.

As far as I could see, during this particular dispute, the aggressive Greens hardly seemed to discriminate at all between Blues and other Greens.

Chlorophanes, I

(15)

February 4, 1958
Barro Colorado

Well! Another terrific rain storm last night, and one of the capture ♀'s, white rufous, drowned!

I watched the wild Green Honeycreepers in the Balsa tree by Chapman House again this evening. Quite a lot in the tree, more than I have ever seen so clearly associated in the wild before (there were at least 3 ♂'s and 1 ♀ in the tree at one time), but they were all certainly hostile to one another. Lots of disputes, like yesterday; and it was obvious that this wild ♀ was also dominant over all the wild ♂'s, being able to chase them all away without any trouble. These disputes were obviously territorial; each bird defending a particular part of the tree.

The most interesting hostile performance this evening was a whole lot of "Tit" Notes. Perhaps started by a ♂ near me, perhaps as a reaction to my presence. Anyhow, all the birds soon started to give "Tit" Notes at moderately frequent intervals. They seemed to be answering one another back and forth, and the whole thing seemed remarkably similar to the bursts of HCN's which flocks of Blue Honeycreepers not infrequently indulge in.

This "Tit" Note pattern may contain a more or less strong escape component; but escape can't be predominant. It is seldom or never accompanied by overt escape; and escaping birds always these disputes are usually silent.

The Green Honeycreepers tonight also defended their territories against intrusion by Blue Honeycreepers.

Chlorophanes, I

16
February 5, 1958
Bravo Colorado

A ♂ in Balba Tree, obviously annoyed at the landing of another pair a few yards away gives R after R w. an apparently perfectly relaxed posture comme ça.

Rump definitely
fluffed

This seems to be significant because the ♂ made no effort to attack the "intruder"; i.e. it would suggest that the attack component is not overwhelmingly predominant in the R, and that the R can occur at generally low intensities.

Lots more fighting in the Balba Tree later on, as usual, but I can add a few new facts and confirm a few old suppositions.

Almost all this fighting takes the form of supplanting attacks & chases (& sometimes repeated chases). Lots of R ♂ still think usually by the aggressive bird). No "fights" this afternoon. Why? Relatively very few V G fluff's, presumably because the attacked bird usually flees as soon as the aggressiveness of its opponent becomes apparent. The only V G fluff's I have seen have been when 2 birds disputed more or less face to face for a second without escape. at least one the V G fluff immediately preceded escape (No display after escape).

One ♂ chased a ♀ again & again, apparently dominant over her. A ♂ Green Honeycreeper just made a supplanting attack on a Bananaquit, which fled immediately.

There was an actual fight, falling through air, between a ♂

Chlorophanes, Feb. 5, 1958, II.

(17)

and a ♀. Accompanied by regular series of hoarse harsh notes presumably the same notes I described on Jan 4, page 12, which I am calling HC. Quite impossible to tell which bird was giving the notes during this fight, may well have been both.

Chlorophanes, I

February 16, 1958

Banjo Colorado

I caught a new ♂ Green Honeycreeper yesterday morning. A young bird, just about completing the molt into adult plumage. Banded yellow left, and put in the large aviary.

The only thing he has done of interest was uttering a lot of "Tut" Notes while sitting moderately alertly on a perch this morning.

A ♀ winter was attracted to the aviary this afternoon when I let loose 2 new Blue Honeycreepers and there was a general commotion (see today's notes on Cyanerpes). She didn't do anything really unusual, but I did notice that she uttered some of her R's from a very fluffed posture with head resting on shoulders, comme ça:

Notice characteristic head shape

This is always (?) present during fluffing of any bird when the bird seems to be "relaxed"

chlorophanes, I

(18)

February 23 1958
Barro Colorado

There hasn't been much new going on for a long time.
I keep catching more Greens (particularly young birds) in the trapping net all the time, (and let them go immediately). This would seem to indicate that the gregarious tendencies of the species are very strong (at least as strong as those of the Blues); but that they are normally thwarted, in the wild, by the even stronger, "hypertrophied", hostile drives - particularly attack.

An adult ♂ in full plumage came to visit this morning and demonstrated some facts particularly clearly. He did a lot of R., and proved conclusively, I think, that the R. is both aggressive and very effective as threat. When he first came, he just stood and looked, and the young ♂ in the aviary just sat and looked back. Then the visitor gave an R. — without other movements — and the young ♂ immediately dove down into the bushes out of sight! Later on the visitor flew around the cage, chasing a ♀ Euphonia in a series of about 8 obviously aggressive flights. He gave an R. each time he started one of these flights!

This species does seem to have an ordinary CN in addition to the "Trit" Notes. I noticed the ♂ uttering these notes this afternoon (with opening & closing of the bill with each note) when he was just flying about the cage in a more or less "relaxed" manner. Sounded just like the "Trit"s, but very much weaker. It is possible that these ordinary CN's will eventually be shown to intergrade with the "Trit"s, but they certainly appear to be quite

Allophantes, Feb. 23, 1958, II

(19)

district in their "typical" form.

Something most peculiar happened this afternoon, which I am not even I was able to follow. Something was uttering single harsh, hoarse, rather short rasping notes (with less rattle undertone than the usual R). These might be transcribed as "Kraaa", and I shall call them Rsp. They were definitely associated, in time, with R's by the captive adult ♂. A few Rsp's occurred by themselves more or less alone (during a general period when R's were common, however), but the usual sequence was an R followed immediately by an Rsp. Sequences such as "R-Rsp-R-Rsp" were also not uncommon. I think that these Rsp's must have been uttered by the captive adult ♂; but I must say that he didn't open his bill at all during the notes - nor could I detect any throat or tail movements! If this note actually was uttered by one of the Greens, I wonder if it is homologous or analogous with the Buzz's of the Flamingos (which it rather resembled in sound, except for the fact that it lacked twang) or, possibly, some of the HCN's or WhN's of the Blues??

Allophantes, I

February 24, 1958,
Barro Colorado.

The young ♂ in the large aviary apparently began a R-Rsp complex performance this morning just when a pair of flamingos came to visit. Much as yesterday, alternating R-Rsp-R-Rsp-R-Rsp-Rsp etc. Again absolutely no outward sign that it was this particular bird who was giving

Chlorophanes, Feb. 24, 1958, II

(20)

III the Rsp Notes. Most peculiar still!

Actually, some of the R's associated with these Rps were rather peculiar in quality. Much softer & probably somewhat slower. More like the ordinary N's in tone. Given with very little opening of the bill. I presume that there are just some sort of variant of the ordinary R (and some quite typical R's were certainly associated with some of these Rps); but I don't know what their significance might be.

Actually, of course, I still have no idea what the peculiar motivation of the Rps might be. Presumably hostile; but how, and just how much??

Chlorophanes, I

March 7, 1958

Bauo Colorado

I have now seen several wild ♀'s visit the aviary and do pronounced G's. This occurred in cool weather, when the birds hadn't been very active, so it couldn't have been a form of "greeting." Must be a ritualized display.

Chlorophanes, I

March 12, 1958

Bauo Colorado

The captive ♂ Green was sitting far apart from the ♀ in the cage this morning when he suddenly went into a long & complex vocal performance, obviously related to some of the R-Rsp performances described above, but rather more elaborate.

Chlorophanes, Mar. 12, 1958, II

(a)

Essentially composed of long R's, and lots of Rps - many more Rps than R's, jumbled in no apparent order, with many Rps occurring without preceding R's. Some of the Rps were preceded by ordinary CN's. Others just occurred in series by themselves, e.g. Rsp-Rsp-Rsp. The intervals between all notes of all birds seemed to be quite variable (except that the Rps tended to follow the other notes very rapidly when they did occur after notes of some other kind — the Rps often sounds like an "exhalation", a letting out of breath after the "inspiration" necessary to produce other notes.)

I think I shall call complex vocal performances like this (and the R-Bzz performance of the just captive ♀ flaming Honeycreeper) "Compound R Songs" (CRSng).

Chlorophanes, I

April 10, 1958
Barro Colorado

Watching a ♂ in a very large very mixed species flock! Not very interesting; but I did note that it uttered lots & lots of simple R's without any attack on other birds. So the R can't always be very aggressive.

Chlorophanes, I

April 19, 1958
Barro Colorado

The captive birds did something peculiar today; which happened so rapidly that I could hardly follow it!

Chlorophanes, Apr. 19, 1958, I.

(22)

The ♀ was just sitting on a twig near the top of the cage, in a rather hunched, rather puffed, posture. The ♂ was down below, probably feeding. Suddenly he flew up to her, landed beside her (parallel and nose or less facing in the same direction), and leaned over her, in a very tall, thin-necked posture, with head & bill nose or less horizontal, belly feathers more or less fluffed (*i.e.* w/ at least a trace of the Vgfluff). Then he sort of jabbed his bill toward her bill, she turned her head so that her bill met his, and then he suddenly flew away.

I think this was an attempt, possibly successful, of the ♂ feeding the ♀.

The actual "feeding", *i.e.* the period when the birds were together, was quite silent, but the ♂ uttered 3 or 4 notes, in a rapid series, just before he flew up to the ♀. Like "Tet" Notes; but softer, less sharp, somehow slightly more pleasant and melodious.

May 5, 1958
Palo Colorado

Chlorophanes, I

I have now caught brief and unrate factors, glimpses of several more cases of the captive ♂ feeding the ♀. Still haven't seen any special preliminaries, if there are any; but it is obvious that the ♂ does not usually make any call beforehand. Nor does the ♀.

I have now heard the ♂ give a brief R - Rep - Rep - Rsp - Rsp - Rsp - Rsp performance. Apparently provoked by, and directed toward, some outside stimulus. This incident

Chlorophanes, May 5, 1958, II

(25)

would seem to definitely prove that the Rop is physically (at least) an independent pattern.

Chlorophanes, I

August 3, 1958
Barro Colorado

Both ♂ and ♀ wild Green Honeycreepers have been coming in to visit the captive Plain and Golden-mantled Tanagers in the large aviary. Probably attracted by the CN's and CNJL's of the tanagers. See also today's notes on Shining Honeycreepers.

Chlorophanes, I

June 13, 1962
Barro Colorado

The old captive ♀ died a year ago. Since then the captive ♂ has been kept in a cage by himself. This morning I shall put a new captive ♀ in with him. This new ♀ has been in a cage by herself for some months.

♀ put in 6:10 a.m. Both birds quit feeding.

6:15 ♂ starts to move around a little. ♀ just now ♀.
Fitters occasional loud single "Tut" Notes

6:20. No change. ♀ just sitting & looking. ♂ keeping as far away from her as possible. In exactly opposite corner of cage.

6:25 Boa picks up old food. Both birds fly about a little. ♂ silent. Then ♂ utters more single loud "Tut" Notes & continues to utter "Tut" Notes after Boa leaves. ♀ just sits silently.

Chlorophanes, Jun. 13, 1965, II

④

6:27 ♂ suddenly starts to utter longer notes. Obviously closely related to "Tsit"s but could be transcribed as "Tsat"s. In moderately rapid series. Then flies to same branch of "Tsat"s tree, elevating. In trace of VG Jff. "Tsat"s audience into brief R as ♂ slides down branch close to ♀. Then R stops, ♂ utters one or more "Facil" Notes again, still in slight VG Jff, leans toward ♀, and touches her bill with his!!! This looked like an attempt to feed the ♀, but the ♂ certainly did not pick up food beforehand. ♂ silent when actually touching ♀. ♀ just peeks toward him, also quite silent. Then ♂ flies off. Resumes behavior as before.

6:35 The ♂ suddenly starts to approach the ♀ again and again. Repeated cop. attempts. Between 6:35 and 7:10 a.m. there at least 22 such attempts!!! Wobbling

up to a climax at the 12th attempt and then declining.

All the attempts were essentially similar in many respects, but there were a few changes as the series progressed.

All attempts were begun by the ♂ flying to the ♀. Sometimes the ♂ flew directly to the ♀. At other times he flew back and forth excitedly, for a few seconds before flying to the ♀. Quiet appeals over to the ♀ were relatively rare during the first 7 or 8 cop. attempts. Normal during the latter attempts. Sometimes the ♂ landed close

beside the ♀. At other times he landed some inches away from her, and then approached her now slowly, on foot. "Close landings" were usual during the later cop attempts; relatively rare during the early attempts. The ♂ never did any pivoting or bowing as he approached the ♀. He always showed a trace of VG Hiss as he stood beside the ♀ and/or approached her on foot. Sometimes these traces were very slight (possibly not necessarily hostile - as the upward stretching of the neck might be nothing more than an attention movement of mounting, and the fluffing of the underparts might be purely ornamental, as well as used in some cases). At other times the VG Hiss was more extreme and more obviously hostile (sometimes accompanied by very frequent WF's as during disputes between several males). Obviously hostile VG Hiss's were characteristic of earlier attempts than later ones.

The ♂ always uttered several "Fee" Notes as he approached ♀. These were always uttered as he flew toward her. Sometimes also when flying back and forth beforehand. Sometimes continued while he stood right beside her immediately before mounting. Not continued during actual mounting, or resumed after dismounting.

These "Fee" Notes were similar to the "Feeet"s uttered before the feeding attempt described above, but shorter, less loud, probably slightly softer. Uttered in rapid series; but rhythm of series quite variable and irregular. Frequently more or less commege: — —

— — — — something about the rhythm was quite reminiscent of "GHAC" of some other species.

These "Fee"s must be primarily sexual. "Feeet"s obviously hostile. "Feeet"s morphologically intermediate between "Fee"s and

Chlorophanes, June 13, 1943, IV.

"Trit". (Conceivably, the "Trit" might be strictly homologous with the PN's of other species.)

Sometimes the ♂ also uttered brief R's, usually in middle "free" flights, while approaching ♀. Apparently perfectly normal hostile R's.

The ♀ usually (always except during some of the very latest attempts - see below) went into an extreme BV-TV posture immediately as soon as ♂ showed any obvious intention of approaching her. A typical BV-TV is sketched (roughly) on p. 24. Bill always pointed strongly by upward. Possibly sometimes approaching vertical. Tail always raised very high also. Breast lowered. Extreme belly-fluffing. During the first few attempts the ♀ kept her wings meeting on her back throughout the period she stayed in BV-TV. During the 7th attempt, however, I noticed that the wings were held out slightly (even before the ♂ attempted to mount). Then often horizontal. This holding out was even more extreme during the 8th attempt. Probably characteristic of almost all the later attempts. Wings always approximately horizontal. Probably or certainly spread to some extent. Absolutely no time of ♀ by the ♀ at any time!!! Resemblant of Ramphocelus!

The ♀ always remained quite silent throughout all the copulatory attempts. She was probably, in fact, silent in all circumstances all morning.

The actual mountings were quite undistinguished. During most attempts, especially the earlier ones, the ♂ mounted more than once. 2, 3, or 4 times during a single attempt.

Post cop patterns were somewhat variable. Sometimes nothing at all. Some times ♀ flew away immediately after an attempt. More often she remained where she was, and the ♂ flew away.
